Causal Inference: Roadmap for Part I

1. Counterfactual framework
2. Relationship to structural models
3. Treatment effects, issue of heterogeneity
4. Treatment parameters of interest
5. Selection problem / sorting problem
6. Overview of possible approaches

Causal Questions

- ▶ Examples of questions in causal inference:
 1. Labor economics: University premium, industry wage gap
 2. Public finance: Impacts of health care expenditures and health insurance on health
 3. Education: If school choice, education reform, and school inputs boost learning
 4. Macroeconomics: If expansionary monetary policy revive a troubling economy
 5. Industrial organization: If a monopolist's price increase lower demand
 6. Environmental economics: If firms' green technology adoption reduce local pollution
- ▶ In causal inference, we want to know the mechanisms behind

Counterfactual Framework

- ▶ D_i : treatment dummy variable for individual i
 - $D_i = 1$ if treated, $= 0$ otherwise
- ▶ Y_{1i} : counterfactual outcome for i if treated
 - i.e., what would have been observed if treated
- ▶ Y_{0i} : counterfactual outcome for i if not treated
 - i.e., what would have been observed if not treated
- ▶ Y_i : observed outcome for i
 - That is,

$$Y_i = Y_{0i} + D_i(Y_{1i} - Y_{0i}) = \begin{cases} Y_{1i} & \text{if } D_i = 1 \\ Y_{0i} & \text{if } D_i = 0 \end{cases}$$

- ▶ Implicit in the notation:
 - No interaction across units (i.e., no GE effects or peer effects)
- ▶ X_i : observed control variables, directly affect Y_{0i} and Y_{1i}

Example: College Premium

- ▶ D_i : college education of individual i
 - $D_i = 1$ if received college degree, $= 0$ if not
- ▶ Y_{1i} : potential wage of i if worked with college degree
- ▶ Y_{0i} : potential wage of i if worked without college degree
- ▶ Y_i : observed wage of i
- ▶ X_i : characteristics in standard wage equation (e.g., age, gender, location, parental education)

Structural Models

- ▶ We now introduce structural models
- ▶ Counterfactual notation can be equivalently written with structural notation

- Example 1: $Y_i = \beta_0 + \beta_1 D_i + X_i \gamma + U_i$

$$Y_{1i} = \beta_0 + \beta_1 + X_i \gamma + U_i$$

$$Y_{0i} = \beta_0 + X_i \gamma + U_i$$

- Example 2: $Y_i = g(D_i, X_i, U_i)$

$$Y_{1i} = g(1, X_i, U_i)$$

$$Y_{0i} = g(0, X_i, U_i)$$

Counterfactual Framework vs. Structural Models

- ▶ There are philosophical differences between counterfactual outcome framework vs. structural models
 - “Effect of causes” (statistical solution) vs. “cause of effects” (scientific solution)

Counterfactual Framework vs. Structural Models

- ▶ There are philosophical differences between counterfactual outcome framework vs. structural models
 - “Effect of causes” (statistical solution) vs. “cause of effects” (scientific solution)
- ▶ Effect of causes:
 - All in black-box
 - Maybe enough in experimental setting (i.e., with randomization)
 - Hard to extrapolate
- ▶ Cause of effects:
 - Want to learn mechanisms behind
 - Use economic theory as guidance
 - Counterfactual analysis: Can forecast effects of treatments that never occurred before

Treatment Effects

- ▶ The treatment effect for individual i can be written as

$$Y_{1i} - Y_{0i}$$

- ▶ Fundamental challenge of causal inference:
 - Y_{1i} and Y_{0i} are not simultaneously observed
 - e.g., same individual's wages with and without college

Treatment Effects

- ▶ The treatment effect for individual i can be written as

$$Y_{1i} - Y_{0i}$$

- ▶ Fundamental challenge of causal inference:
 - Y_{1i} and Y_{0i} are not simultaneously observed
 - e.g., same individual's wages with and without college
- ▶ One solution:

$$E[Y_{1i} - Y_{0i}] = E[Y_{1i}] - E[Y_{0i}]$$

- cf. $Q_{\tau}(Y_{1i} - Y_{0i}) \neq Q_{\tau}(Y_{1i}) - Q_{\tau}(Y_{0i})$
- cf. Distributional treatment effects

Treatment Effect Heterogeneity

- ▶ Let

$$\Delta_i = Y_{1i} - Y_{0i}$$

- ▶ Q: How does Δ_i vary with i ?

Treatment Effect Heterogeneity

- ▶ Let

$$\Delta_i = Y_{1i} - Y_{0i}$$

- ▶ Q: How does Δ_i vary with i ?

1. Homogeneous treatment effect: $\Delta_i = \Delta$ (doesn't vary with i)

- Example: $Y_i = \beta_0 + \beta_1 D_i + X_i \gamma + U_i$ then

$$Y_{1i} - Y_{0i} = \beta_1$$

- Another example: $Y_i = \beta_0 + \beta_1 D_i + g(X_i) + U_i$

Treatment Effect Heterogeneity

2. Homogeneous treatment effect conditional on X_i : $\Delta_i = \Delta(X_i)$

- That is, if $X_i = X_j$ then $Y_{1i} - Y_{0i} = Y_{1j} - Y_{0j}$ (i.e., individuals with same X have same effect)
- Example: $Y_i = \beta_0 + \beta_1 D_i X_i + X_i \gamma + U_i$ then

$$Y_{1i} - Y_{0i} = \beta_1 X_i$$

- Another example: $Y_i = g(D_i, X_i) + U_i$ then

$$Y_{1i} - Y_{0i} = g(1, X_i) - g(0, X_i)$$

Treatment Effect Heterogeneity

3. Heterogeneous treatment effect: Δ_i varies with i , even conditional on X_i

- Example: $Y_i = \beta_0 + \beta_{1i}D_i + X_i\gamma + U_i$ then

$$Y_{1i} - Y_{0i} = \beta_{1i}$$

- Another example: $Y_i = g(D_i, X_i, U_i)$ then

$$Y_{1i} - Y_{0i} = g(1, X_i, U_i) - g(0, X_i, U_i)$$

Selection Bias and Sorting Gain

- ▶ Two subcases of Case 3:
 - (a) $Y_{1i} - Y_{0i}$ is independent of D_i conditional on X_i
 - (b) $Y_{1i} - Y_{0i}$ is correlated with D_i conditional on X_i
- ▶ This distinction is different from the one involved in usual selection bias discussion
 - Selection bias: Y_{0i} is correlated of D_i even conditional on X_i
 - No selection bias: Y_{0i} is independent of D_i conditional on X_i
 - ◊ e.g., $Y_{0i} = \beta_0 + X_i\gamma + U_i$ with $E[U_i|D_i, X_i] = E[U_i|X_i]$
 - ◊ The usual conditional independence condition addresses selection bias
- ▶ (a) vs. (b): whether there is “essential heterogeneity” (and sorting on gain) or not
 - Case (b) is when individuals sort themselves based on gain (not only based on baseline outcome Y_0)
 - More later

Objects of Interest

- ▶ Homogeneous treatment effects (Cases 1 and 2):
 - Δ , $\Delta(X_i)$, or $E[\Delta(X_i)]$
- ▶ Heterogeneous treatment effects (Case 3(a)):
 - $E[\Delta_i]$, $E[\Delta_i|X_i]$ (or more)
- ▶ Heterogeneous treatment effects (Case 3(b)):
 - Not clear
 - e.g., local average treatment effect (LATE) (later)

Examples of Mean Treatment Parameters

- ▶ Average treatment effect (ATE): $E[Y_{1i} - Y_{0i}]$
- ▶ ATE on the treated (TT): $E[Y_{1i} - Y_{0i} | D_i = 1]$
- ▶ ATE on the un-treated (TUT): $E[Y_{1i} - Y_{0i} | D_i = 0]$
- ▶ ATE conditional on X_i : $E[Y_{1i} - Y_{0i} | X_i]$
- ▶ TT conditional on X_i : $E[Y_{1i} - Y_{0i} | D_i = 1, X_i]$
- ▶ TUT conditional on X_i : $E[Y_{1i} - Y_{0i} | D_i = 0, X_i]$

Heterogenous Treatment Effects

- ▶ Homogeneous treatment effects (Case 1):
 - $ATE = TT = TUT = ATE(X_i) = TT(X_i) = TUT(X_i)$
- ▶ Homogeneous treatment effects conditional on X_i (Case 2):
 - $ATE(X_i) = TT(X_i) = TUT(X_i)$ but possible that $ATE \neq TT \neq TUT$
- ▶ Heterogeneous treatment effects (Case 3(a)):
 - Same as Case 2
- ▶ Heterogeneous treatment effects (Case 3(b)):
 - $ATE \neq TT \neq TUT \neq ATE(X_i) \neq TT(X_i) \neq TUT(X_i)$

Evaluation Problems

- ▶ Homogeneous treatment effects (Case 1): Selection bias

$$\begin{aligned} & E[Y_i|D_i = 1] - E[Y_i|D_i = 0] \\ &= E[Y_{1i} - Y_{0i}|D_i = 1] + E[Y_{0i}|D_i = 1] - E[Y_{0i}|D_i = 0] \\ &= \Delta + E[Y_{0i}|D_i = 1] - E[Y_{0i}|D_i = 0] \end{aligned}$$

- $E[Y_{0i}|D_i = 1] - E[Y_{0i}|D_i = 0]$ is selection bias
- e.g., individuals with higher “baseline” tend to attend college
- Same in Case 2

Evaluation Problems

- ▶ Heterogeneous treatment effects (Case 3):

$$\begin{aligned} & E[Y_i|D_i = 1] - E[Y_i|D_i = 0] \\ &= E[Y_{1i} - Y_{0i}|D_i = 1] + E[Y_{0i}|D_i = 1] - E[Y_{0i}|D_i = 0] \\ &= E[Y_{1i} - Y_{0i}] + E[Y_{1i} - Y_{0i}|D_i = 1] - E[Y_{1i} - Y_{0i}] \\ &+ E[Y_{0i}|D_i = 1] - E[Y_{0i}|D_i = 0] \end{aligned}$$

- $E[Y_{1i} - Y_{0i}|D_i = 1] - E[Y_{1i} - Y_{0i}]$ is the sorting gain
- e.g., individuals with higher college premium tend to attend college
- Sorting gain is not zero in Case 3(b)

Overview of Possible Approaches

- ▶ How to recover some mean treatment parameters?
 1. Randomized experiment
 2. Matching / conditional independence assumption
 3. Difference-in-differences (DD)
 4. Regression discontinuity (RD)
 5. Instrumental variables (IV) methods
- ▶ These methods allow heterogeneous treatment effects
 - Which treatment parameter is recovered depends on the method
 - Sometime we use structural models (e.g., linear model) for each method
 - ◊ This means we impose more restrictions
 - ◊ Treatment effects may even be restricted to be homogeneous

Randomized Experiment

- ▶ When D_i is randomized, it satisfies $(Y_{1i}, Y_{0i}) \perp D_i$
 - e.g., random lottery for college (among eligible applicants)
- ▶ Then,

$$E[Y_{di}|D_i = d] = E[Y_{di}] \text{ for } d = 1, 0$$

- ▶ Random assignment eliminates selection bias and sorting gain:

$$\begin{aligned} E[Y_i|D_i = 1] - E[Y_i|D_i = 0] &= E[Y_{1i}|D_i = 1] - E[Y_{0i}|D_i = 0] \\ &= E[Y_{1i}] - E[Y_{0i}] \\ &= E[Y_{1i} - Y_{0i}] \end{aligned}$$

- ▶ Simple difference-in-mean estimator can be used:

$$\frac{\sum_{i=1}^n Y_i 1\{D_i = 1\}}{\sum_{i=1}^n 1\{D_i = 1\}} - \frac{\sum_{i=1}^n Y_i 1\{D_i = 0\}}{\sum_{i=1}^n 1\{D_i = 0\}}$$

Matching and Conditional Independence

- ▶ First, we consider the approach that imposes conditional independence assumption:

$$(Y_{1i}, Y_{0i}) \perp D_i | X_i$$

- i.e., conditional on X_i (e.g., demographics, previous educations), we assume D_i (e.g., college) is as if randomized
 - Idea of matching: conditional on X_i , the two groups are balanced
 - This can be weakened to mean independence
- ▶ Another assumption needed: For any X_i ,

$$0 < \Pr[D_i = 1 | X_i] < 1$$

- Common support (or overlap) assumption
- Related to “no multicollinearity” assumption

Matching and Conditional Independence

- ▶ Under these assumption,

$$\begin{aligned} & E[Y_i|D_i = 1, X_i] - E[Y_i|D_i = 0, X_i] \\ &= E[Y_{1i}|D_i = 1, X_i] - E[Y_{0i}|D_i = 0, X_i] \\ &= E[Y_{1i}|X_i] - E[Y_{0i}|X_i] \\ &= E[Y_{1i} - Y_{0i}|X_i] \end{aligned}$$

- ▶ X_i can include many covariates, even continuous variables
 - May not be appealing in practice
- ▶ Surprising result:

$$(Y_{1i}, Y_{0i}) \perp D_i | X_i \iff (Y_{1i}, Y_{0i}) \perp D_i | P(X_i)$$

where $P(X_i) = \Pr[D_i = 1|X_i]$ is the propensity score

- This is the idea of propensity score matching
- As long as the propensity of receiving treatment is the same, the two groups are balanced

Matching and Conditional Independence

- ▶ That is,

$$\begin{aligned} & E[Y_i|D_i = 1, P(X_i)] - E[Y_i|D_i = 0, P(X_i)] \\ &= E[Y_{1i} - Y_{0i}|P(X_i)] \end{aligned}$$

- Again, the common support assumption is implicitly used
- ▶ Various estimators can be used
 - Regression-based estimator
 - Inverse probability weighting estimator
 - Matching estimator

Matching and Conditional Independence

- ▶ Much weaker independence assumption:

$$E[Y_{0i}|D_i = 1, X_i] = E[Y_{0i}|D_i = 0, X_i]$$

- ▶ Then,

$$\begin{aligned} & E[Y_i|D_i = 1, X_i] - E[Y_i|D_i = 0, X_i] \\ &= E[Y_{1i}|D_i = 1, X_i] - E[Y_{0i}|D_i = 0, X_i] \\ &= E[Y_{1i}|D_i = 1, X_i] - E[Y_{0i}|D_i = 1, X_i] \\ &= E[Y_{1i} - Y_{0i}|D_i = 1, X_i] \end{aligned}$$

Before-After Analysis (Event Studies)

- ▶ Suppose we observe individuals before/after treatment
 - e.g., before and after job training
- ▶ $D_i = 1$ if i receives treatment at given time
- ▶ Y_{it} : outcome in period t ; Y_{1it} and Y_{0it} are potential outcomes
 - $t = b$ (before) or a (after)
 - Y_{ia} : outcome in period after the treatment ($Y_{ia} = Y_{1ia}$)
 - Y_{ib} : outcome in period before the treatment ($Y_{ib} = Y_{0ib}$)
- ▶ Assumption: $E[Y_{0ib}|D_i = 1] = E[Y_{0ia}|D_i = 1]$
- ▶ Then,

$$\begin{aligned} E[Y_{ia}|D_i = 1] - E[Y_{ib}|D_i = 1] &= E[Y_{1ia}|D_i = 1] - E[Y_{0ib}|D_i = 1] \\ &= E[Y_{1ia}|D_i = 1] - E[Y_{0ia}|D_i = 1] \\ &= E[Y_{1ia} - Y_{0ia}|D_i = 1] \end{aligned}$$

- Treatment effect on the treated (after the treatment)

Difference-in-Differences

- ▶ Is the assumption above plausible?
 - e.g., time effects, age effects...
- ▶ Suppose we observe treated/untreated individuals, before/after treatment
- ▶ Common trend assumption:

$$E[Y_{0ia} - Y_{0ib} | D_i = 1] = E[Y_{0ia} - Y_{0ib} | D_i = 0]$$

- e.g., “baseline” wage trends are same btw treatment and control groups
- Let $\Delta Y_{0i} = Y_{0ia} - Y_{0ib}$, then this assumption (conditional on X_i) is conditional indep in terms of ΔY_{0i}

Difference-in-Differences

- ▶ Common trend assumption:

$$E[Y_{0ia} - Y_{0ib} | D_i = 1] = E[Y_{0ia} - Y_{0ib} | D_i = 0]$$

- ▶ Then,

$$\begin{aligned} & E[Y_{ia} - Y_{ib} | D_i = 1] - E[Y_{ia} - Y_{ib} | D_i = 0] \\ &= E[Y_{1ia} - Y_{0ib} | D_i = 1] - E[Y_{0ia} - Y_{0ib} | D_i = 0] \\ &= E[Y_{1ia} - Y_{0ia} | D_i = 1] \\ &\quad + E[Y_{0ia} - Y_{0ib} | D_i = 1] - E[Y_{0ia} - Y_{0ib} | D_i = 0] \\ &= E[Y_{1ia} - Y_{0ia} | D_i = 1] \end{aligned}$$

- Treatment effect on the treated (after the treatment)

Regression Discontinuity

- ▶ Let R_i be the running variable
 - e.g., college test score or eligibility score
- ▶ Suppose

$$D_i = \begin{cases} 1 & \text{if } R_i \geq r_0 \\ 0 & \text{if } R_i < r_0 \end{cases}$$

- ▶ Comparison:

$$\begin{aligned} & \lim_{\epsilon \downarrow 0} E[Y_i | R_i = r_0 + \epsilon] - \lim_{\epsilon \downarrow 0} E[Y_i | R_i = r_0 - \epsilon] \\ &= \lim_{\epsilon \downarrow 0} E[Y_{1i} | R_i = r_0 + \epsilon] - \lim_{\epsilon \downarrow 0} E[Y_{0i} | R_i = r_0 - \epsilon] \\ &= E[Y_{1i} | R_i = r_0] - E[Y_{0i} | R_i = r_0] \end{aligned}$$

- ▶ Local polynomial estimators (with chosen window of R_i)

Instrumental Variables Methods

- ▶ Suppose there exists an instrumental variable (IV) that satisfies
 - $cov(D, Z) \neq 0$
 - $Z \perp (Y_0, Y_1)$
 - ◊ i.e., Exclusion restriction: The only difference created by IV is in the likelihood of receiving treatment
- ▶ e.g., distance to nearest college or density of colleges
- ▶ e.g., random lottery for college (but potential non-compliance)

Challenges with Essential Heterogeneity

► Consider

$$\begin{aligned} Y &= Y_0 + D(Y_1 - Y_0) \\ &= E[Y_0] + DE[Y_1 - Y_0] + (\varepsilon + \eta D) \end{aligned}$$

where $\varepsilon = Y_0 - E[Y_0]$ and $\eta = (Y_1 - Y_0) - E[Y_1 - Y_0]$

- Q: Does linear IV recover a parameter of interest?
- If Δ const, classical IV results hold and IV recovers treatment effects
 - If Δ hetero and if essential hetero, classical IV results not hold and IV not recover interpretable parameters
 - If Δ hetero and if essential hetero, and if impose selection model (i.e., LATE monotonicity), IV recovers interpretable parameters (may/may not be of interest)

Challenges with Essential Heterogeneity

- ▶ Case 1: Δ const (i.e., $\eta = 0$)
 - Then, $\text{cov}(Z, Y_0) = 0$ implies $\text{cov}(Z, \varepsilon) = 0$
 - Then,

$$\frac{\text{cov}(Y, Z)}{\text{cov}(D, Z)} = E[Y_1 - Y_0]$$

- If there is another IV, it identifies the same parameter
- ▶ Case 3: Δ varies even conditional on X
 - In general, we cannot identify $E[Y_1 - Y_0]$
 - We need $E[\varepsilon + \eta D|Z] = 0$
 - $E[\varepsilon|Z] = 0$, but

$$E[\eta D|Z] = E[\eta|D = 1, Z]P[D = 1|Z]$$

and even if $E[\eta|Z] = 0$, $E[\eta|D = 1, Z] \neq 0$ (i.e., essential hetero)

Challenges with Essential Heterogeneity

- ▶ Three approaches:
 1. LATE and MTE approaches (selection model approach)
 - ◇ May focus on different parameters
 2. Nonparametric IV approach (may be restrictive)
 - ◇ May be restrictive to allow for essential heterogeneity
 3. Nonparametric control function approach

Local Average Treatment Effect (LATE)

- ▶ Suppose Z_i is binary
 - e.g., close to college ($Z_i = 1$) or distant to college ($Z_i = 0$)
- ▶ We cannot recover ATE $E[Y_{1i} - Y_{0i}]$ in general
- ▶ Define counterfactual treatment: D_{1i} and D_{0i}
 - e.g., $D_{1i} = 1$ (or 0): i would have attended (or not attend) college, had i lived close to college
- ▶ “Monotonicity” assumption: $D_{1i} \geq D_{0i}$ for all i or $D_{1i} \leq D_{0i}$ for all i
 - e.g., no individual who would have attended college if living far from college but have not attended if living close to college
 - i.e., no defiers $\{D_{1i} = 0, D_{0i} = 1\}$

Local Average Treatment Effect (LATE)

► Then,

$$\frac{E[Y_i|Z_i = 1] - E[Y_i|Z_i = 0]}{E[D_i|Z_i = 1] - E[D_i|Z_i = 0]} = E[Y_{1i} - Y_{0i}|D_{1i} = 1, D_{0i} = 0]$$

- $\frac{E[Y_i|Z_i=1]-E[Y_i|Z_i=0]}{E[D_i|Z_i=1]-E[D_i|Z_i=0]}$ is the Wald estimand (or TSLS estimand)
 - $E[Y_{1i} - Y_{0i}|D_{1i} = 1, D_{0i} = 0]$ is called LATE
 - Individuals who behave like $\{D_{1i} = 1, D_{0i} = 0\}$ are called “compliers”
 - e.g., individuals who would have attended college if living close to college but have not attended if living far
- Need to understand which parameter you are estimating!

Marginal Treatment Effects (MTE)

► Suppose

$$D_i = 1[h(Z_i) \geq V_i]$$

- The structure can be motivated by agent's optimizing behavior
 - ◊ e.g., attend college when net utility is positive
- This model is equivalent to “monotonicity” assumption above!

► Assume Z_i is continuous, and define MTE as

$$E[Y_{1i} - Y_{0i} | V_i = v]$$

- ATE for those who are indifferent (i.e., those on the “margin”)

Marginal Treatment Effects (MTE)

- ▶ MTE:

$$E[Y_{1i} - Y_{0i} | V_i = v]$$

- ▶ Note that

$$\begin{aligned} E[Y_{1i} - Y_{0i} | D_{z'i} = 1, D_{zi} = 0] &= E[Y_{1i} - Y_{0i} | h(z') \geq V_i, h(z) < V_i] \\ &= E[Y_{1i} - Y_{0i} | h(z) < V_i \leq h(z')] \end{aligned}$$

therefore

$$E[Y_{1i} - Y_{0i} | V_i = h(z)] = \lim_{h(z') \rightarrow h(z)} E[Y_{1i} - Y_{0i} | h(z) < V_i \leq h(z')]$$

Marginal Treatment Effects (MTE)

- ▶ MTE can be viewed as a building block to generate various treatment parameters:

$$\tau_k = \int \omega_k(v, z) E[Y_{1i} - Y_{0i} | V_i = v] dv$$

- $\omega_k(z, v)$ is known weight specific to the parameter of interest
- ▶ For example,

$$ATE = E[Y_{1i} - Y_{0i}] = \int_0^1 E[Y_{1i} - Y_{0i} | V_i = v] dv$$

$$\begin{aligned} LATE &= E[Y_{1i} - Y_{0i} | D_{zi} = 1, D_{z'i} = 0] \\ &= \int_{P(z')}^{P(z)} \frac{E[Y_{1i} - Y_{0i} | V_i = v]}{P(z) - P(z')} dv \end{aligned}$$

$$ATT = E[Y_{1i} - Y_{0i} | D_i = 1] = \int_0^{P(z)} \frac{E[Y_{1i} - Y_{0i} | V_i = v]}{P[D = 1]} dv$$

Marginal Treatment Effects (MTE)

- ▶ Moreover, MTE can be recovered by

$$E[Y_{1i} - Y_{0i} | V_i = p] = \frac{\partial E[Y_i | P(Z_i) = p]}{\partial p}$$

where $P(X_i) = \Pr[D_i = 1 | X_i]$

- Continuity of $P(Z_i)$ and thus continuity of Z_i is important
 - ◊ e.g., Z_i is actual distance to nearest college
- Support of $P(Z_i)$ and thus support of Z_i can be important, depending on parameters
 - ◊ e.g., for ATE, $P(Z_i) \rightarrow 1, 0$, which means $Z_i \rightarrow +\infty, -\infty$
- ▶ MTE itself can be a parameter of interest
 - Non-constant MTE reflects heterogeneity
- ▶ MTE can be estimated nonparametrically, but typically after imposing more structure

Nonparametric IV Approach

▶ Let

$$Y_i = g(D_i, U_i)$$

- Want to know g because $Y_{1i} = g(1, U_i)$ and $Y_{0i} = g(0, U_i)$
- ▶ Let Z_i be an IV that satisfies $E[U_i|Z_i] = 0$
- ▶ Assume U_i is scalar and $g(D_i, \cdot)$ is strictly monotonic
 - e.g., $Y_i = g(D_i) + U_i$
 - If U_i is continuous, Y_i should be continuous

Nonparametric IV Approach

- ▶ Then

$$0 = E[U_i|Z_i] = E[g^{-1}(D_i, Y_i)|Z_i]$$

- e.g., $0 = E[U_i|Z_i] = E[Y_i - g(D_i)|Z_i]$
- ▶ If we additionally impose completeness condition (i.e., Z_i is relevant for D_i in “nonparametric sense”), then g can be recovered from

$$E[Y_i|Z_i] = E[g(D_i)|Z_i]$$

- ▶ Estimation is more challenging due to the ill-posed inverse problem
 - $E[\cdot]$ is smooth, so its inverse is non-smooth
 - Related to “small denominator” problem
 - Regularization is needed

Nonparametric Control Function Approach

- ▶ Assume

$$D_i = h(Z_i, V_i)$$

where V_i is scalar and $h(Z_i, \cdot)$ is strictly monotonic

- e.g., $D_i = h(Z_i) + V_i$
 - If V_i is continuous, D_i should be continuous (e.g., years of education)
- ▶ Then, construct a CF:

$$V_i = h^{-1}(Z_i, D_i)$$

- e.g., $V_i = D_i - h(Z_i)$

Nonparametric Control Function Approach

- ▶ Assume $E[U_i|V_i, Z_i] = E[U_i|V_i]$
- ▶ Let $Y_i = g(D_i) + U_i$ for simplicity
- ▶ Then

$$\begin{aligned} E[Y_i|D_i, Z_i] &= g(D_i) + E[U_i|D_i, Z_i] = g(D_i) + E[U_i|V_i, Z_i] \\ &= g(D_i) + E[U_i|V_i] = g(D_i) + \lambda(V_i) \end{aligned}$$

- ▶ Equivalently

$$Y_i = g(D_i) + \lambda(V_i) + \eta_i$$

where $E[\eta_i|D_i, Z_i] = 0$

- ▶ Nonparametrically estimate g and λ after estimating V_i
